

EDMG Studio

Repo-backed app summary

One-page repo-backed summary of the canonical app surface in D:/DWCTGenerativeSoundStudio

What It Is

EDMG Studio is the repo's canonical desktop product: an Electron shell with a React UI and a local FastAPI backend for a DAW-like workflow from audio ingest to planning, rendering, and outputs. It brings local AI, ComfyUI, FFmpeg, and optional EDMG Core into one Studio surface.

Who It's For

Explicit persona: Not found in repo. Docs and workflow naming point to music-video creators or producers who want a local-first desktop pipeline for audio-driven visuals.

What It Does

- Project-based workflow with per-project assets, analysis, timeline, jobs, and outputs.
- Upload audio and reference images, then run audio analysis and transcription.
- Generate plan variants and creative direction, then apply them to the timeline.
- Edit tracks, overlays, masks, and camera keyframes; preview frames and short segments.
- Render through ComfyUI stills/motion or internal/proxy video paths.
- Track jobs with live logs, cancel/retry, clean restart, and checkpoint resume.
- Browse videos, images, and Deforum exports; manage setup, models, and optional cloud bundles.

How It Works

- Electron main process (main.mjs) starts the backend, stores Studio Home and AI settings, and exposes desktop IPC.
- React/Vite UI (src/App.tsx, src/pages/*, src/components/api.ts) drives Projects, Workspace, Timeline, Render, Queue, Outputs, Setup, Models, Cloud, and Settings.
- FastAPI backend (python_backend/edmg_studio_backend/app.py) owns project, setup, model, render, preview, export, and cloud routes.
- File-backed stores (store/projects.py, store/jobs.py) persist each project under data/projects/<id> with assets/, analysis/, outputs/, and jobs/.
- WorkerManager runs queued jobs; services handle AI, ComfyUI pooling, internal/proxy render, compositor overlays, FFmpeg assembly, setup, and EDMG Core.
- Data flow: audio/refs -> analysis/transcription -> plan/creative direction -> timeline -> render job -> videos/images/Deforum exports plus history, logs, and checkpoints.

How To Run

1. Install Python 3.10-3.13 and Node.js LTS.
2. From repo root, run RUN_ME.bat on Windows or ./run_me.sh on macOS/Linux; both hand off to tools/launcher_gui.py, the canonical dev launcher.
3. In Studio, set Studio Home, then use Setup -> Full Setup to install/check the backend bundle, Ollama/model, ComfyUI Portable, FFmpeg, and optional EDMG Core.

Repo evidence: README_STUDIO.md; README.md; studio/edmg-studio/README.md; RUN_ME.bat; run_me.sh; tools/launcher_gui.py; studio/edmg-studio/main.mjs; studio/edmg-studio/src/App.tsx; studio/edmg-studio/python_backend/edmg_studio_backend/app.py; store/projects.py; store/jobs.py.
